

Graph Algorithms

Problems on Graphs

2/51

What kind of problems do we want to solve on/via graphs?

- is the graph fully-connected?
- can we remove an edge and keep it fully-connected?
- is one vertex reachable starting from some other vertex?
- what is the cheapest cost path from  $v$  to  $w$ ?
- which vertices are reachable from  $v$ ? (transitive closure)
- is there a cycle that passes through all vertices? (circuit)
- is there a tree that links all vertices? (spanning tree)
- what is the minimum spanning tree?
- what is the maximal flow through a graph?
- ...
- can a graph be drawn in a plane with no crossing edges? (planar graphs)
- are two graphs "equivalent"? (isomorphism)

Graph Algorithms

3/51

In this course we examine algorithms for

- connectivity (simple graphs)
- path finding (simple/directed graphs)
- minimum spanning trees (weighted graphs)
- shortest path (weighted graphs)
- maximum flow (weighted graphs)

We already looked at *depth-first* (DFS) and *breadth-first* (BFS) traversal ...

Other DFS Examples

4/51

Other problems to solve via DFS graph search

- checking for the existence of a cycle
- determining which connected component each vertex is in

Exercise #1: Buggy Cycle Check

5/51

A graph has a *cycle* if

- it has a path of length  $> 1$
- with start vertex  $src$  = end vertex  $dest$
- and without using any edge more than once

We are not required to give the path, just indicate its presence.

The following DFS cycle check has two bugs. Find them.

```
hasCycle(G):
|   Input   graph G
|   Output true if G has a cycle, false otherwise
|
|   choose any vertex  $v \in G$ 
|   return dfsCycleCheck(G,v)
|
dfsCycleCheck(G,v):
|   mark v as visited
|   for each  $(v,w) \in \text{edges}(G)$  do
|   |   if w has been visited then    // found cycle
|   |   |   return true
|   |   else if dfsCycleCheck(G,w) then
|   |   |   return true
|   end for
|   return false                      // no cycle at v
```

---

1. Only one connected component is checked.
2. The loop

**for each**  $(v,w) \in \text{edges}(G)$  **do**

should exclude the neighbour of v from which you just came, so as to prevent a single edge  $w-v$  from being classified as a cycle.

---

## Computing Connected Components

7/51

Problems:

- how many connected subgraphs are there?
- are two vertices in the same connected subgraph?

Both of the above can be solved if we can

- build an array, one element for each vertex V
  - indicating which connected component V is in
  - `componentOf[ ]` ... array  $[0..nV-1]$  of component IDs
- 

## ... Computing Connected Components

8/51

Algorithm to assign vertices to connected components:

```
components(G):
|   Input   graph G
|
|   for all vertices  $v \in G$  do
|   |   componentOf[v] = -1
|   end for
|   compID = 0
|   for all vertices  $v \in G$  do
|   |   if componentOf[v] = -1 then
|   |   |   dfsComponents(G,v,compID)
|   |   |   compID = compID + 1
|   |   end if
```

end for

```
dfsComponents(G,v,id):  
    componentOf[v]=id  
    for all vertices w adjacent to v do  
        if componentOf[w]=-1 then  
            dfsComponents(G,w,id)  
        end if  
    end for
```

Exercise #2: Connected components

Trace the execution of the algorithm

- 1. on the graph shown below
- 2. on the same graph but with the dotted edges added

Consider neighbours in ascending order

1.

[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]
-1	-1	-1	-1	-1	-1	-1	-1
0	-1	-1	-1	-1	-1	-1	-1
0	-1	0	-1	-1	-1	-1	-1
0	0	0	-1	-1	-1	-1	-1
0	0	0	1	-1	-1	-1	-1
...							
0	0	0	1	1	2	2	2

2.

[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]
-1	-1	-1	-1	-1	-1	-1	-1
0	-1	-1	-1	-1	-1	-1	-1
0	0	-1	-1	-1	-1	-1	-1
0	0	0	-1	-1	-1	-1	-1
...							
0	0	0	0	0	1	1	1

Hamiltonian and Euler Paths

Hamiltonian Path and Circuit

Hamiltonian path problem:

- find a simple path connecting two vertices  $v, w$  in graph  $G$
- such that the path includes each *vertex* exactly once

If  $v = w$ , then we have a *Hamiltonian circuit*

Simple to state, but difficult to solve (*NP*-complete)

Many real-world applications require you to visit all vertices of a graph:

- Travelling salesman
- Bus routes
- ...

Problem named after Irish mathematician, physicist and astronomer Sir William Rowan Hamilton (1805 - 1865)

## ... Hamiltonian Path and Circuit

13/51

Graph and two possible Hamiltonian paths:

## ... Hamiltonian Path and Circuit

14/51

Approach:

- generate all possible simple paths (using e.g. DFS)
- keep a counter of vertices visited in current path
- stop when find a path containing  $V$  vertices

Can be expressed via a recursive DFS algorithm

- similar to simple path finding approach, except
  - keeps track of path length; succeeds if length =  $v$
  - resets "visited" marker after unsuccessful path

## ... Hamiltonian Path and Circuit

15/51

Algorithm for finding Hamiltonian path:

`visited[]` // array `[0..nV-1]` to keep track of visited vertices

```
hasHamiltonianPath(G,src,dest):
|   for all vertices  $v \in G$  do
|       visited[v]=false
|   end for
|   return hamiltonR(G,src,dest,#vertices(G)-1)
```

```
hamiltonR(G,v,dest,d):
|   Input G      graph
|           v      current vertex considered
|           dest  destination vertex
|           d      distance "remaining" until path found
|
|   if v=dest then
|       if d=0 then return true else return false
```

```

else
    visited[v]=true
    for each (v,w)∈edges(G) ∧ ¬visited[w] do
        if hamiltonR(G,w,dest,d-1) then
            return true
        end if
    end for
end if
visited[v]=false           // reset visited mark
return false

```

### Exercise #3: Hamiltonian Path

16/51

Trace the execution of the algorithm when searching for a Hamiltonian path from 1 to 6:

Consider neighbours in ascending order

1-0-2-3-4-5-6	d≠0
1-0-2-3-4-5-7-8-9	no unvisited neighbour
1-0-2-3-4-5-7-9-8	no unvisited neighbour
1-0-2-3-4-7-5-6	d≠0
1-0-2-3-4-7-8-9	no unvisited neighbour
1-0-2-3-4-7-9-8	no unvisited neighbour
1-0-2-3-4-8-7-5-6	d≠0
1-0-2-3-4-8-7-9	no unvisited neighbour
1-0-2-3-4-8-9-7-5-6	✓

Repeat on your own with src=0 and dest=6

### ... Hamiltonian Path and Circuit

18/51

Analysis: worst case requires  $(V-1)!$  paths to be examined

Consider a graph with isolated vertex and the rest fully-connected

Checking `hasHamiltonianPath(g,x,0)` for any  $x$

- requires us to consider every possible path
- e.g 1-2-3-4, 1-2-4-3, 1-3-2-4, 1-3-4-2, 1-4-2-3, ...
- starting from any  $x$ , there are  $3!$  paths  $\Rightarrow 4!$  total paths
- there is no path of length 5 in these  $(V-1)!$  possibilities

There is no known simpler algorithm for this task  $\Rightarrow NP$ -hard.

Note, however, that the above case could be solved in constant time if we had a fast check for 0 and  $x$  being in the same connected component

## Euler Path and Circuit

19/51

*Euler path* problem:

- find a path connecting two vertices  $v,w$  in graph  $G$
- such that the path includes each *edge* exactly once  
(note: the path does not have to be simple  $\Rightarrow$  can visit vertices more than once)

If  $v = w$ , then we have an *Euler circuit*

Euler Path: 4-3-1-5-2-1

Euler Circuit: 1-2-5-4-3-1

Many real-world applications require you to visit all edges of a graph:

- Postman
- Garbage pickup
- ...

Problem named after Swiss mathematician, physicist, astronomer, logician and engineer Leonhard Euler (1707 - 1783)

## ... Euler Path and Circuit

20/51

One possible "brute-force" approach:

- check for each path if it's an Euler path
- would result in factorial time performance

Can develop a better algorithm by exploiting:

*Theorem.* A graph has an *Euler circuit* if and only if it is connected and all vertices have even degree

*Theorem.* A graph has a *non-circuitous Euler path* if and only if it is connected and exactly two vertices have odd degree

## Exercise #4: Euler Paths and Circuits

21/51

Which of these two graphs have an Euler path? an Euler circuit?

No Euler circuit

Only the second graph has an Euler path, e.g. 2-0-1-3-2-4-5

## ... Euler Path and Circuit

23/51

Assume the existence of  $\text{degree}(g, v)$  (degree of a vertex, cf. problem set week 6)

Algorithm to check whether a graph has an Euler path:

```

hasEulerPath(G,src,dest):
    Input  graph G, vertices src,dest
    Output true if G has Euler path from src to dest
           false otherwise

    if src≠dest then
        if degree(G,src) or degree(G,dest) is even then
            return false
        end if
    else if degree(G,src) is odd then
        return false
    end if
    for all vertices v∈G do
        if v≠src and v≠dest and degree(G,v) is odd then
            return false
        end if
    end for
    return true

```

## ... Euler Path and Circuit

24/51

Analysis of hasEulerPath algorithm:

- assume that connectivity is already checked
- assume that degree is available via  $O(1)$  lookup
- single loop over all vertices  $\Rightarrow O(V)$

If degree requires iteration over vertices

- cost to compute degree of a single vertex is  $O(V)$
- overall cost is  $O(V^2)$

$\Rightarrow$  problem tractable, even for large graphs (unlike Hamiltonian path problem)

For the keen, a linear-time (in the number of edges,  $E$ ) algorithm to compute an Euler path is described in [Sedgewick] Ch.17.7.

## Directed Graphs

In our previous discussion of graphs:

- an edge indicates a relationship between two vertices
- an edge indicates nothing more than a relationship

In many real-world applications of graphs:

- edges are directional ( $v \rightarrow w \neq w \rightarrow v$ )
- edges have a *weight* (cost to go from  $v \rightarrow w$ )

... Directed Graphs (Digraphs)

27/51

Example digraph and adjacency matrix representation:

Undirectional  $\Rightarrow$  symmetric matrix  
Directional  $\Rightarrow$  non-symmetric matrix

Maximum #edges in a digraph with V vertices:  $V^2$

... Directed Graphs (Digraphs)

28/51

Terminology for digraphs ...

*Directed path*: sequence of  $n \geq 2$  vertices  $v_1 \rightarrow v_2 \rightarrow \dots \rightarrow v_n$

- where  $(v_i, v_{i+1}) \in edges(G)$  for all  $v_i, v_{i+1}$  in sequence
- if  $v_1 = v_n$ , we have a *directed cycle*

*Reachability*:  $w$  is reachable from  $v$  if  $\exists$  directed path  $v, \dots, w$

Digraph Applications

29/51

Potential application areas:

Domain	Vertex	Edge
Web	web page	hyperlink
scheduling	task	precedence
chess	board position	legal move
science	journal article	citation
dynamic data	malloc'd object	pointer
programs	function	function call

## ... Digraph Applications

30/51

Problems to solve on digraphs:

- is there a directed path from  $s$  to  $t$ ? (transitive closure)
- what is the shortest path from  $s$  to  $t$ ? (shortest path)
- are all vertices mutually reachable? (strong connectivity)
- how to organise a set of tasks? (topological sort)
- which web pages are "important"? (PageRank)
- how to build a web crawler? (graph traversal)

## Digraph Representation

31/51

Similar set of choices as for undirectional graphs:

- array of edges (directed)
- vertex-indexed adjacency matrix (non-symmetric)
- vertex-indexed adjacency lists

$V$  vertices identified by  $0 \dots V-1$

## Reachability

## Transitive Closure

33/51

Given a digraph  $G$  it is potentially useful to know

- is vertex  $t$  reachable from vertex  $s$ ?

Example applications:

- can I complete a schedule from the current state?
- is a malloc'd object being referenced by any pointer?

How to compute transitive closure?

## ... Transitive Closure

34/51

One possibility:

- implement it via `hasPath( $G, s, t$ )` (itself implemented by DFS or BFS algorithm)
- feasible if `reachable( $G, s, t$ )` is infrequent operation

What if we have an algorithm that frequently needs to check reachability?

Would be very convenient/efficient to have:

```
reachable(G,s,t):
|   return G.tc[s][t]    // transitive closure matrix
```

Of course, if  $V$  is *very* large, then this is not feasible.

Exercise #5: Transitive Closure Matrix

35/51

Which reachable  $s \dots t$  exist in the following graph?

Transitive closure of example graph:

... Transitive Closure

37/51

**Goal:** produce a matrix of reachability values

- if  $tc[s][t]$  is 1, then  $t$  is reachable from  $s$
- if  $tc[s][t]$  is 0, then  $t$  is not reachable from  $s$

So, how to create this matrix?

Observation:

$\forall i,s,t \in \text{vertices}(G)$ :  
 $(s,i) \in \text{edges}(G) \text{ and } (i,t) \in \text{edges}(G) \Rightarrow tc[s][t] = 1$

$tc[s][t] = 1$  if there is a path from  $s$  to  $t$  of length 2 ( $s \rightarrow i \rightarrow t$ )

... Transitive Closure

38/51

If we implement the above as:

```
make tc[][] a copy of edges[][]
for all i in vertices(G) do
  for all s in vertices(G) do
    for all t in vertices(G) do
      if tc[s][i] = 1 and tc[i][t] = 1 then
        tc[s][t] = 1
      end if
    end for
  end for
end for
```

then we get an algorithm to convert edges into a *tc*

This is known as *Warshall's algorithm*

... Transitive Closure

How it works ...

After iteration 1,  $tc[s][t]$  is 1 if

- either  $s \rightarrow t$  exists or  $s \rightarrow 0 \rightarrow t$  exists

After iteration 2,  $tc[s][t]$  is 1 if any of the following exist

- $s \rightarrow t$  or  $s \rightarrow 0 \rightarrow t$  or  $s \rightarrow l \rightarrow t$  or  $s \rightarrow 0 \rightarrow l \rightarrow t$  or  $s \rightarrow l \rightarrow 0 \rightarrow t$

Etc. ... so after the  $V^{th}$  iteration,  $tc[s][t]$  is 1 if

- there is any directed path in the graph from  $s$  to  $t$

Exercise #6: Transitive Closure

Trace Warshall's algorithm on the following graph:

1<sup>st</sup> iteration  $i=0$ :

tc	[0]	[1]	[2]	[3]
[0]	0	1	1	1
[1]	1	1	1	1
[2]	0	1	0	0
[3]	0	0	0	0

2<sup>nd</sup> iteration  $i=1$ :

tc	[0]	[1]	[2]	[3]
[0]	1	1	1	1
[1]	1	1	1	1
[2]	1	1	1	1
[3]	0	0	0	0

3<sup>rd</sup> iteration  $i=2$ : unchanged

4<sup>th</sup> iteration  $i=3$ : unchanged

... Transitive Closure

Cost analysis:

- storage: additional  $V^2$  items (each item may be 1 bit)
- computation of transitive closure:  $V^3$
- computation of `reachable()`:  $O(I)$  after having generated `tc[ ][ ]`

Amortisation: would need many calls to `reachable()` to justify other costs

Alternative: use DFS in each call to `reachable()`

Cost analysis:

- storage: cost of queue and set during `reachable`
- computation of `reachable()`: cost of DFS =  $O(V^2)$  (for adjacency matrix)

## Digraph Traversal

43/51

Same algorithms as for undirected graphs:

### **depthFirst(v):**

1. mark `v` as visited
2. for each  $(v,w) \in \text{edges}(G)$  do
  - if `w` has not been visited then
  - depthFirst(w)**

### **breadth-first(v):**

1. enqueue `v`
2. while queue not empty do
  - dequeue `v`
  - if `v` not already visited then
  - mark `v` as visited
  - enqueue each vertex `w` adjacent to `v`

## Example: Web Crawling

44/51

**Goal:** visit every page on the web

**Solution:** breadth-first search with "implicit" graph

```
webCrawl(startingURL):
|   mark startingURL as alreadySeen
|   enqueue(Q,startingURL)
|   while Q is not empty do
|       |   nextPage=dequeue(Q)
|       |   visit nextPage
|       |   for each hyperLink on nextPage do
|       |       |   if hyperLink not alreadySeen then
|       |       |       mark hyperLink as alreadySeen
|       |       |       enqueue(Q,hyperLink)
|       |       end if
|       end for
|   end while
```

`visit` scans page and collects e.g. keywords and links

## PageRank

45/51

**Goal:** determine which Web pages are "important"

**Approach:** ignore page contents; focus on hyperlinks

- treat Web as graph: page = vertex, hyperlink = di-edge
- pages with many incoming hyperlinks are important
- need to computing "incoming degree" for vertices

Problem: the Web is a *very* large graph

- approx.  $10^{14}$  pages,  $10^{15}$  hyperlinks

Assume for the moment that we could build a graph ...

Most frequent operation in algorithm "Does edge (v,w) exist?"

... PageRank

46/51

Simple PageRank algorithm:

```
PageRank(myPage) :
|   rank=0
|   for each page in the Web do
|   |   if linkExists(page,myPage) then
|   |   |   rank=rank+1
|   |   end if
|   end for
```

Note: requires *inbound* link check (not outbound as assumed above for cost of representation)

... PageRank

47/51

$V$  = # pages in Web,  $E$  = # hyperlinks in Web

Costs for computing PageRank for each representation:

Representation	linkExists(v,w)	Cost
Adjacency <i>matrix</i>	edge[v][w]	$I$
Adjacency <i>lists</i>	inLL(list[v],w)	$\cong E/V$

Not feasible ...

- adjacency matrix ...  $V \cong 10^{14} \Rightarrow$  matrix has  $10^{28}$  cells
- adjacency list ...  $V$  lists, each with  $\cong 10$  hyperlinks  $\Rightarrow 10^{15}$  list nodes

So how to really do it?

... PageRank

48/51

Approach: the random web surfer

- if we randomly follow links in the web ...
- ... more likely to re-discover pages with many inbound links

```
curr=random page, prev=null
for a long time do
|   if curr not in array ranked[] then
|   |   rank[curr]=0
```

```

end if
rank[curr]=rank[curr]+1
if random(0,100)<85 then           // with 85% chance ...
    prev=curr
    curr=choose hyperlink from curr // ... crawl on
else
    curr=random page              // avoid getting stuck
    prev=null
end if
end for

```

Could be accomplished while we crawl web to build search index

---

## Exercise #7: Implementing Facebook

49/51

Facebook could be considered as a giant "social graph"

- what are the vertices?
- what are the edges?
- are edges directional?

What kind of algorithm would ...

- help us find people that you might like to "befriend"?
- 

## Tips for Week 7 Problem Set

50/51

Main theme: *Graph traversal, digraphs*

- Test your understanding of Euler/Hamiltonian paths/cycles
  - Test your understanding of directed graphs
  - Algorithms:
    - correct the "buggy" cycle check from above
    - maintain "connected component array" as part of graph ADT implementation
  - *Do the online mock test*
  - *Review all concepts, data structures, algorithms from weeks 2-7*
- 

## Summary

51/51

- Graph traversal: cycle check, connected components
  - Hamiltonian paths/circuits, Euler paths/circuits
  - Digraphs: representations, applications
  - Warshall's algorithm to compute reachability
  - Suggested reading (Sedgewick):
    - Hamiltonian/Euler paths ... Ch.17.7
    - Digraphs ... Ch.19.1-19.3
-
