Because Perl makes heavy use of strings, regular expressions are a very important component of the language.

in conditional expressions to test whether a string matches a

They can be used:

- pattern
  e.g. checking the contents of a string
- if (\$name =~ /[0-9]/) { print "name contains digit" • in assignments to modify the value of a string
- e.g. convert McDonald to MacDonald \$name =~ s/Mc/Mac/;
  - e.g. convert to upper case
    \$string =~ tr/a-z/A-Z/;

Because Perl makes heavy use of strings, regular expressions are a very important component of the language.

They can be used:

- in conditional expressions to test whether a string matches a pattern
  - e.g. checking the contents of a string

```
if (name = (0-9)) { print "name contains digit\n";
```

• in assignments to modify the value of a string

e.g. convert McDonald to MacDonald

```
$name =~ s/Mc/Mac/;
```

Perl extends POSIX regular expressions with some shorthand:

```
\d matches any digit, i.e. [0-9]
\D matches any non-digit, i.e. [^0-9]
\w matches any "word" char, i.e. [a-zA-Z_0-9]
\W matches any non "word" char, i.e. [^a-zA-Z_0-9]
\s matches any whitespace, i.e. [ \t\n\r\f]
\S matches any non-whitespace, i.e. [^ \t\n\r\f]
```

Perl also adds some new anchors to regexps:

```
\b matches at a word boundary
\B matches except at a word boundary
```

And generalises the repetition operators:

```
patt* matches 0 or more occurences of patt
patt+ matches 1 or more occurences of patt
patt? matches 0 or 1 occurence of patt
patt\{n,m\} matches between n and m occurences of patt
```

The default semantics for pattern matching is "first, then largest". E.g. /ab+/ matches *abbb*abbbb not *abbbabbbb* or abbb*abbbb* 

A pattern can also be qualified so that it looks for the shortest match.

If the repetition operator is followed by ? the "first, then shortest" string that matches the pattern is chosen.

E.g. /ab+?/ would match abbbabbbb

Regular expressions can be formed by interpolating strings in between  $/ \dots /$ .

Example:

```
$pattern = "ab+";
$replace = "Yod";
$text = "abba";

$text =~ s/$pattern/$replace/;
# converts "abba" to "Yoda"
```

Note: Perl doesn't confuse the use of \$ in \$var and abc\$, because the anchor occurs at the end.

# Using Matching Results

In a scalar context matching & substitute operators return how many times the match/substitute succeeded.

This allows them to be used as the controlling expression in if/while statements.

For example:

```
print "Destroy the file system? "
$answer = <STDIN>;
if ($answer =~ /yes||ok|affirmative/i) {
    system "rm -r /";
}
s/[aeiou]//g or die "now vowels to replace";
```

# Using Matching Results

\$string = "-5==10zzz200\_";
@numbers = \$string =~ /\d+/g;
print join(",", @numbers), "\n";

In a list context the matching operators returns a list of the matched strings.

For example:

# prints 5,10,200

```
If the regex contains ()s only the captured text is returned

$string = "Bradley, Marion Zimmer";
($family_name, $given_name) = $string =~ /([^,]*), (\S+)/;
print "$given_name $family_name\n";
# prints Marion Bradley
```

#### Pattern Matcher

A Perl script to accept a pattern and a string and show the match (if any):

You might find this a useful tool to test out your understanding of regular expressions.
